Class 15 RNA Seq

Stefanie Hodapp (PID: A53300084)

11/17/2021

Load the contData and colData

We need 2 things - 1: count data - 2: colData (the metadata that tells us about the deisgn of the experiment)

```
counts <- read.csv("airway_scaledcounts.csv", row.names=1)
metadata <-  read.csv("airway_metadata.csv")
```

```
head(counts)
```

```

## 6 SRR1039517 treated  N080611 GSM1275871
```

Q1. How many genes are in this dataset? 38694

```
nrow(counts)
```

```
## [1] 38694
```

Q2. How many 'control' cell lines do we have 4

```
View(metadata)
```

Check the correspondance of the metadata with the counts data

```
all(metadata$id == colnames(counts))
```

```
## [1] TRUE
```

Compare control to treated

Q3. How would you make the above code in either approach more robust?

First we need to access all the control columns in our counts data

```
control.inds <- metadata$dex == "control"
metadata[control.inds, ]$id
```

```
## [1] "SRR1039508" "SRR1039512" "SRR1039516" "SRR1039520"
```

Use these ids to access just the control columns of our 'counts' data

```
control.mean <- rowMeans(counts[ , control.inds])
head(control.mean)
```

```
## ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
##          900.75            0.00          520.50          339.75           97.25
## ENSG00000000938
##            0.75
```

Do the same for the drug treated...

Q4. Follow the same procedure for the treated samples (i.e. calculate the mean per gene across drug treated samples and assign to a labeled vector called treated.mean)

```
treated.inds <- metadata$dex == "treated"
treated.mean <- rowMeans(counts[ , treated.inds])
head(treated.mean)
```

```
## ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
##          658.00            0.00          546.00          316.50           78.75
## ENSG00000000938
##            0.00
```

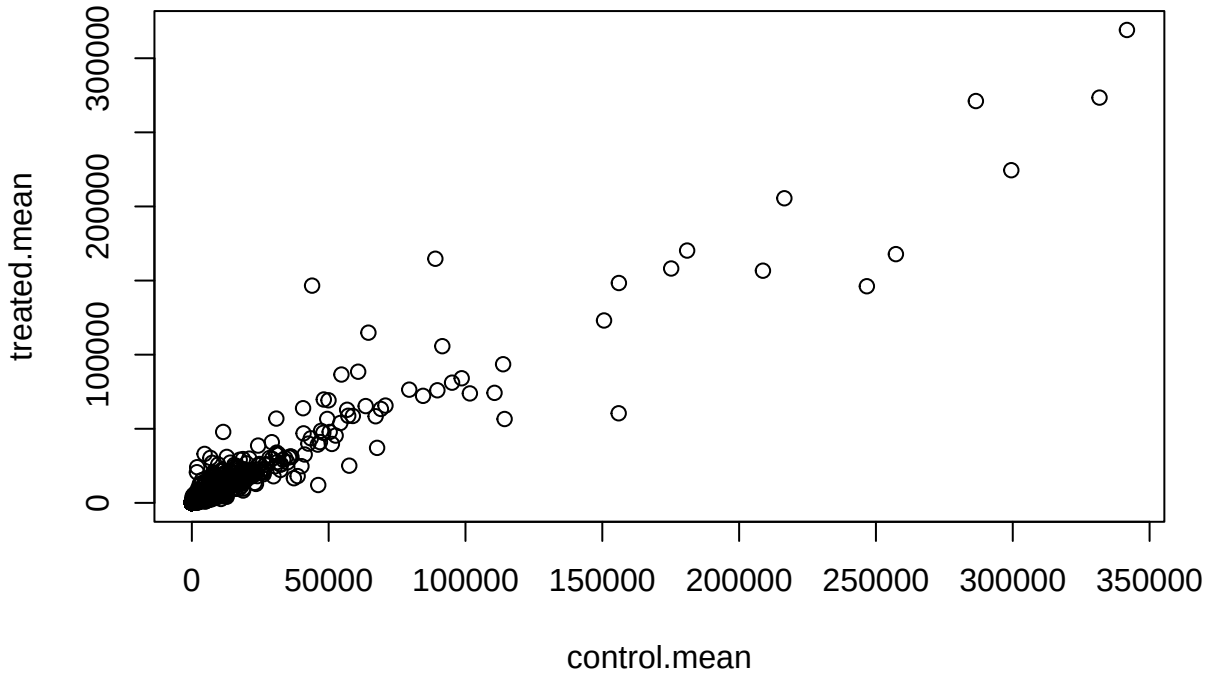
We will combine our meancount data for bookkeeping purposes.

```
meancounts <- data.frame(control.mean, treated.mean)
```

Compare the control and treated

Q5 (a). Create a scatter plot showing the mean of the treated samples against the mean of the control samples. Your plot should look something like the following.

```
plot(meancounts)
```



Q5 (b).You could also use the ggplot2 package to make this figure producing the plot below. What geom_?() function would you use for this plot?

```
# ggplot(meancounts, aes(control.mean, treated.mean)) + geom_point()
```

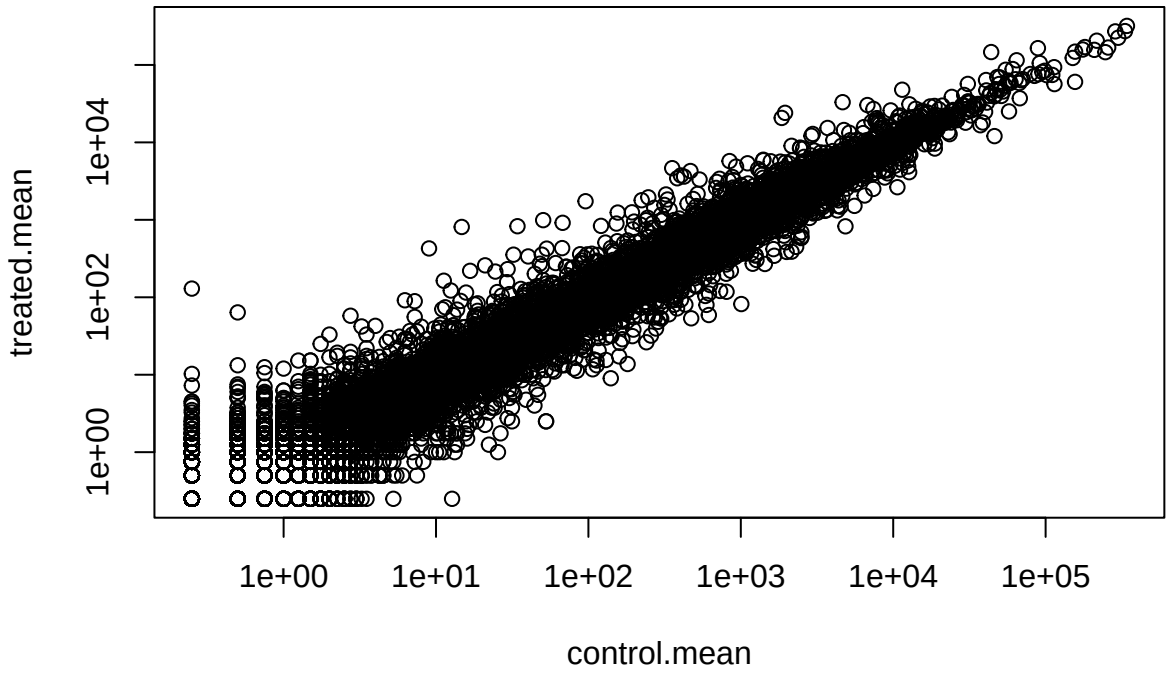
Q6. Try plotting both axes on a log scale. What is the argument to plot() that allows you to do this?

Try plotting both axes on a log scale

```
plot(meancounts, log="xy")
```

```
## Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted
## from logarithmic plot
```

```
## Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted
## from logarithmic plot
```



Let's calculate the log2 fold change between control and dex-treated samples.

```
meancounts$log2fc <- log2(meancounts[,"treated.mean"]/meancounts[,"control.mean"])
head(meancounts)
```

```
##                 control.mean treated.mean      log2fc
## ENSG00000000003       900.75       658.00 -0.45303916
## ENSG00000000005         0.00         0.00         NaN
## ENSG00000000419       520.50       546.00  0.06900279
## ENSG00000000457       339.75       316.50 -0.10226805
## ENSG00000000460        97.25        78.75 -0.30441833
## ENSG00000000938         0.75         0.00        -Inf
```

We need to drop the zero count genes/rows!

```
head(meancounts[,1:2] == 0)
```

```
##                 control.mean treated.mean
## ENSG00000000003        FALSE        FALSE
## ENSG00000000005         TRUE         TRUE
## ENSG00000000419        FALSE        FALSE
## ENSG00000000457        FALSE        FALSE
```

```
## ENSG00000000460        FALSE        FALSE
## ENSG00000000938        FALSE         TRUE
```

> Q7. What is the purpose of the arr.ind argument in the which() function call above? Why would we then take the first column of the output and need to call the unique() function? arr.ind=TRUE returns the positions in a matrix that are "TRUE" as integers. The unique() function will delete duplicate rows (e.g. genes with zero counts in both control and treated samples).

The 'which()' functions tell us the indices of TRUE entries in a logical vector

```
inds <- which(meancounts[,1:2] == 0, arr.ind=TRUE)
head(inds)
```

```
##                 row col
## ENSG00000000005   2   1
## ENSG00000004848  65   1
## ENSG00000004948  70   1
## ENSG00000005001  73   1
## ENSG00000006059 121   1
## ENSG00000006071 123   1
```

I only care about the rows here (if there is a zero in any column I will exclude this row eventually)

```
to.rm <- unique(sort(inds[,"row"]))
```

Remove the genes with zero expression from our meancounts data

```
mycounts <- meancounts[-to.rm,]
head(mycounts)
```

```
##                 control.mean treated.mean      log2fc
## ENSG00000000003       900.75       658.00 -0.45303916
## ENSG00000000419       520.50       546.00  0.06900279
## ENSG00000000457       339.75       316.50 -0.10226805
## ENSG00000000460        97.25        78.75 -0.30441833
## ENSG00000000971      5219.00      6687.50  0.35769358
## ENSG00000001036      2327.00      1785.75 -0.38194109
```

We now have "r nrow(mycounts)' genes remaining

```
nrow(mycounts)
```

```
## [1] 21817
```

> Q8. Using the up.ind vector above can you determine how many up regulated genes we have at the greater than 2 fc level?

```
up.ind <- mycounts$log2fc > 2
sum(up.ind)
```

```
## [1] 250
```

What percentage is this?

```
round((sum(up.ind) / nrow(mycounts))*100, 2)
```

```
## [1] 1.15
```

> Q9. Using the down.ind vector above can you determine how many down regulated genes we have at the greater than 2 fc level?

```
down.ind <- mycounts$log2fc < (-2)
sum(down.ind)
```

```
## [1] 367
```

```
round((sum(down.ind) / nrow(mycounts))*100, 2)
```

```
## [1] 1.68
```

> Q10. Do you trust these results? Why or why not? I don't trust that these results are significant as they they only take into account fold change and not p-values (i.e. significance). Genes exhibiting a 2-fold change may not be significant.

DESeq2 analysis

```
library(DESeq2)
```

```

Let's save our results to date

```
write.csv(res, file="allmyresults.csv")
```

Pathway Analysis

Let's try to bring some biology insight back into this work. For this we will start with KEGG.

```
library(pathview)
```

```
## ##############################################################################
## Pathview is an open source software package distributed under GNU General
## Public License version 3 (GPLv3). Details of GPLv3 is available at
## http://www.gnu.org/licenses/gpl-3.0.html. Particullary, users are required to
## formally cite the original Pathview paper (not just mention it) in publications
## or products. For details, do citation("pathview") within R.
##
## The pathview downloads and uses KEGG data. Non-academic uses may require a KEGG
## license agreement (details at http://www.kegg.jp/kegg/legal.html).
## ##############################################################################
```

```
library(gage)
```

```
##
```

```
library(gageData)
```

```
data(kegg.sets.hs)

# Examine the first 2 pathways in this kegg set for humans
head(kegg.sets.hs, 2)
```

```
## $`hsa00232 Caffeine metabolism`
## [1] "10"   "1544" "1548" "1549" "1553" "7498" "9"

```

Before we can use KEGG we need to get our gene identifiers in the correct format for KEGG, which is ENTREZ format in this case.

```
res$entrez <- mapIds(org.Hs.eg.db,
                     keys=row.names(res),
                     keytype="ENSEMBL",
                     column="ENTREZID",
                     multiVals="first")
```

```
## 'select()' returned 1:many mapping between keys and columns
```

```
res$genename <- mapIds(org.Hs.eg.db,
                     keys=row.names(res),
                     keytype="ENSEMBL",
                     column="GENENAME",
                     multiVals="first")
```

```
## 'select()' returned 1:many mapping between keys and columns
```

The main gage() function requires a named vector of fold changes, where the names of the values are the Entrez gene IDs.

Note that we used the mapIDs() function above to obtain Entrez gene IDs (stored in res$entrez) and we have the foldchanges result

```
foldchanges = res$log2FoldChange
names(foldchanges) = res$entrez
head(foldchanges)
```

```
##        7105       64102        8813       57147       55732        2268
## -0.35070302          NA  0.20610777  0.02452695 -0.14714205 -1.73228897
```

Now, let's run the gage pathway analysis.

```
# Get the results
keggres = gage(foldchanges, gsets=kegg.sets.hs)
```

We can look at the attributes() of this

```
attributes(keggres)
```

```
## $names
## [1] "greater" "less"    "stats"
```

```
# Look at the first three down (less) pathways
head(keggres$less, 3)
```

```
##                                      p.geomean stat.mean        p.val

```

Let's try out the pathview() function from the pathview package to make a pathway plot with our RNA-Seq expression results shown in color.

To begin with lets manually supply a pathway.id (namely the first part of the "hsa05310 Asthma") that we could see from the print out above.

```
pathview(gene.data=foldchanges, pathway.id="hsa05310")
```

```
## 'select()' returned 1:1 mapping between keys and columns
```

```
## Info: Working in directory /Users/stefaniehodapp/Documents/BGGN213_Bioinformatics/Class 15
```

```
## Info: Writing image file hsa05310.pathview.png
```
